Abstract

The melting temperature (T_m) of ionic liquids (ILs) was estimated with a group-interaction contribution method. This temperature is very important for modeling solid-liquid equilibrium and selecting ionic liquids as reaction media, among other things. The proposed method, based on the group-interaction contribution approach, uses two-order contributions and a correction

term. A comprehensive database of 684 ionic liquids with different molecular structures was used to obtain all interaction contribution parameters and correction terms for all groups in the ionic liquids, including a wide range of cation and anion groups. The results showed that with an average absolute relative deviation of 5.04% and a correlation coefficient of 0.85, this linear model represents a reliable and simple approach for the estimation of the melting temperature of diverse ionic liquids based on knowledge of their molecular structure. Taking into account isomerism, it represents an advantage over traditional group contribution methods.

Keywords: Group-Interaction contribution, Ionic liquids, Melting temperature, Molecular structure, Property estimation.

1. Introduction

The development of less-polluting solvents and safe processes is nowadays a high priority on the agenda for "green chemistry". There is a pressing need to rethink the design of unsafe chemical processes so that younger generations inherit a healthy and safer environment. In recent years, ionic liquids, salts that are liquids at low temperatures [1], have received the most attention as alternatives to volatile organic solvents in numerous fields. These include reactive chemistry, mineral processing, and separation processes. The fact that ionic liquids are generally viewed as safe and environmentally friendly is attributed to their negligible vapor pressure and wide liquid range [2].

However, the widespread industrial use of ILs is tributary to the knowledge of their thermal, physical, chemical, thermodynamic, and transport properties. The present study is focused on the estimation of the melting point of a variety of ionic liquids by means of the group interaction contribution (GIC) method. Melting occurs when the molecules or ions comprising a solid fall out of their crystal structures to become disordered liquids [3]. In relation to ionic liquids, the melting temperature is important in determining the liquid us range (thus, the use of ILs as reaction media) as well as modeling the solid-liquid equilibrium of systems involving this class of compounds.

Different approaches have been proposed in the literature for predicting the melting point of ionic liquids. Group Contribution (GC) and Quantitative Structure-Property Relationship (QSPR) emerged as the most commonly used methods for ILs' melting point estimation. Other methods include Artificial Neural Network, COSMO-RS, Chemical homology, and machine learning. More details on various approaches for the prediction of the melting point of ionic liquids can be found in the review paper by Valderrama [4]. This author further discusses fundamental issues related to this property and provides an in-depth analysis of the different

predictive tools that have been proposed by various researchers. The reported correlation coefficient (R^2) ranged between 0.54 and 0.93, while the average absolute relative deviation (AARD) was between 2.5 and 29.3%.

In this study, a comprehensive data set has been used to develop a predictive model for ionic liquids based on Group–interaction contributions (GIC). To the best of our knowledge, this is the first account of the use of GIC for predicting the melting point of ionic liquids. It is worth noting that Group-interaction contribution (GIC) methods were derived to address the major limitation of conventional group contribution methods [5], i.e., the inability to distinguish between isomers. Thus, the quest for more accurate predictions motivated this study, in which an approach similar to that proposed by Marrero and Pardillo [6] is used. Altogether, 684 ILs based on various cations and anions have been used to develop the proposed GIC model.

2. Methodology

2.1 Data Set

In order to develop the GIC-based model presented in this study, a large database was considered. Large databases are advisable as they ensure a wide applicability range for the developed correlations. Altogether, the database comprised 684 ionic liquids, ranging from 180.65 to 495,050 K. These melting points were obtained from the work published by Zhang and co-researchers [7] and [8]. For obvious reasons, some ionic liquids have two or more different melting temperatures reported by different groups. Bearing in mind the non-existence of a recommended standard procedure for melting point measurements, no ground could be found to select the more reliable data points. Hence, all reported data for melting points were considered. This explains why the number of data points is larger than that of ionic liquids.

Tables 1 and 2 show all the anions and cations involved in the investigated ionic liquids. There were altogether 18 cation and 44 anion types represented. It emerges that experimental studies related to T_m measurements mostly covered imidazolium, ammonium, phosphonium, piperidinium, and pyrrolidinium-based ionic liquids. This could be expected as the most commercially available ionic liquids comprise these cations.

Table 1: Cations encountered in the studied ionic liquids: the percentage indicates the number among the given cation out of the total number of ILs comprising the data base.

Class of ILs	Abbreviation	No of ILs
Imidazolium	IM	230

bis((perfluoroethane)sulfonyl)imide	BETI	06
bis(fluorosulfonyl) imide	FSI	02

2.2. Proposed model

In the present study, molecular structure was related to the melting point of ionic liquids through a three-level estimation: first-order contribution and second-order contribution. This was done according to principles outlined in previous works owed to Marrero and Pardillo [5] and Mokadem et al. [9]. The method suggested by these researchers is articulated around these three points.

As shown in the literature, a property denoted T_m can be modeled via GIC by means of the following correlations:

$$T_m(K) = A + \sum_j n_j \Delta C_j + \sum_k m_k \Delta D_k + \sum_i f_i \Delta C_i \quad (1)$$

where n_j and m_k are the number of first and second-order groups of type j and k in the molecule respectively; and ΔC_j are the group-interaction contributions for the first and ΔD_k , ΔC_i second-order group respectively, and A and f_i are adjustable model parameters.

The step procedure shown in Figure 2 was used to determine the adjustable parameters and group-interaction values for the model.

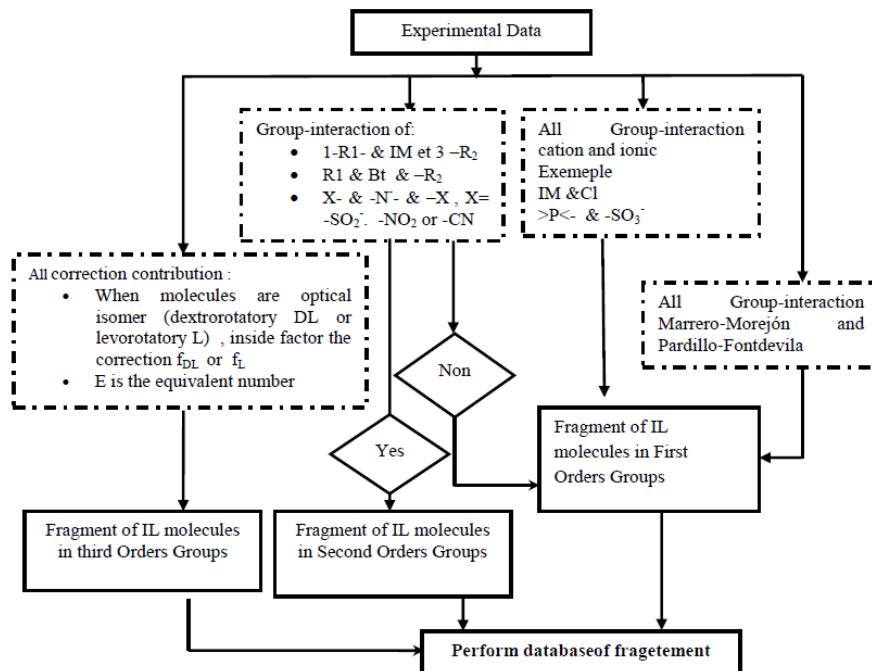

Figure 2: Computational algorithm for the GIC model

The objective function, the average absolute deviation (AAD), the percent average relative deviation ($\%AARD$) and the correlation coefficient (R^2) were calculated as a means to assess the performance of the developed model, according to the following equation:

$$F = \sum_{i=1}^n (Tm_i^{exp} - Tm_i^{cal})^2 \quad (2)$$

$$AAD = \frac{100}{n} \sum_{i=1}^n |Tm_i^{exp} - Tm_i^{cal}| \quad (3)$$

$$\%AARD = \frac{100}{n} \sum_{i=1}^n \left| \frac{Tm_i^{cal}}{Tm_i^{exp}} - 1 \right| \quad (4)$$

$$R^2 = 1 - \frac{\sum_{i=1}^n \left| \frac{Tm_i^{cal}}{(Tm_i^{ext} - Tm_i^{exp})} \right|^2}{\sum_{i=1}^n \left| \frac{Tm_i^{cal}}{(Tm_i^{exp} - \text{average}(Tm_i^{exp}))} \right|^2} \quad (5)$$

As part of this study, the validation set comprised 505 data points used to test the developed model. Although the correlation and validation sets were selected randomly, care was taken to ensure that during the modeling process, molecules were decomposed into fragments, with all the groups found to have adequate frequency in the selected ILs.

3. Results and discussion

In order to estimate the melting temperature of ILs, the contributions of the group interaction were calculated from the experimental data of different ionic liquids according to the procedure presented in Figure 5. The final equation for this model, obtained through linear regression, was as follows:

$$Tm(K) = 292.160 + \sum_j n_j \Delta C_j + \sum_k m_k \Delta D_k + f_E \times E + f_L + f_{DL} \quad (6)$$

However, in the case of optical isomers (dextrorotatory DL or levorotatory L), the corresponding correction factors were optimized as $f_L = -127.516$ K and $f_{DL} = 0$ K to be used in this equation:

$$Tm(K) = 292.160 + \sum_j n_j \Delta C_j + \sum_k m_k \Delta D_k - 69.91 \times E - 127.51 \times f_L \quad (7)$$

First - and second-order group-interaction contribution parameters are reported in Tables 3 and 4, respectively. First-order group interactions were determined for all sub-structures comprising the examined ionic liquids and cations. Second-order group interaction contribution values were obtained for all functional groups and anions available in the

ionic liquids' database. Altogether, 268 first-order and 16 second-order interaction parameters were obtained.

As shown in Figure 4 presenting the performance of the newly developed model, the latter is consistent with experimental data for a large portion of data points, although large discrepancies are observed for some T_m values as 68.51K. Such large deviations were also observed in similar studies as pointed out by Valderrama (2014) [9] who reported differences between experimental and predicted melting points as high as 180 K.

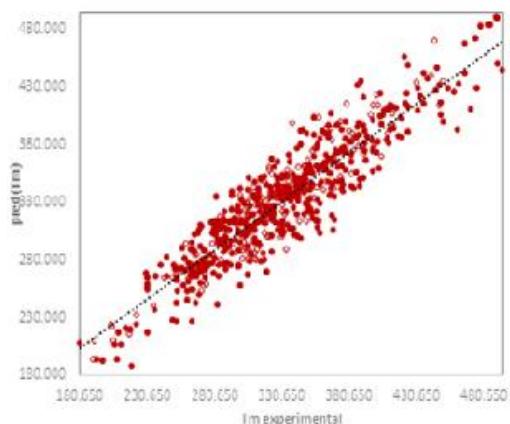

Figure 3: Comparison between experimental and predicted T_m data for the training set (●) and test set (○).

For a total of 684 experimental melting points, the average relative deviation (AARD) and correlation coefficient (R^2) for this model were calculated as 5.04 % and 0.85 respectively, while the average absolute deviation between calculated and experimental data was 68.69 K. These values indicate an acceptable level of both accuracy and predictability. A further comparison is made in Table 5 between the performance of this model and that of other methods reported in the literature.

Table 5: Comparison between the model proposed in this study and those reported in the literature.

With respect to previous models, no improvement in either accuracy or predictability can be claimed from this present study. However, its merits are undoubtedly the extensive nature of the database used (the largest database in Table 6) as well as the ability to differentiate between isomers. The latter cannot be achieved with conventional group contribution methods. AARD between model predictions and experimental data is provided in Table 6 for all classes of ionic liquids contained in the database. It appears that the model developed in this study exhibits the best performance for imidazolium-based ionic liquids, which represent 43% of all investigated ILs. This can be regarded as significant, given the popularity of this class of ionic liquids. The worst results are those associated with butyrolactam-based ILs.

Table 6: Deviations between experimental and predicted melting temperatures for various classes of ILs

Class of ILs	Abbreviation	No of ILs	%AARD

More insight into the performance of the new GIC model is given in the appendix as supplementary materials. These consist of a table presenting the calculated and experimental values for all 684 ionic liquids considered in this study. Additionally, a working example is provided to illustrate the use of the GIC model.

Conclusion

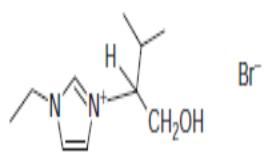

Unlike conventional group interaction methods, the new approach presented in this study takes isomerism into account. A wide applicability range, acceptable accuracy, and good predictive ability represent its remarkable features. A wide applicability range is owed to the extensive database used, comprising altogether 1073 data points for 684 ionic liquids, as well as the variety of cations and anions involved in the modelling process. Acceptably low deviations between experimental values and those predicted in this study (AARD=5 %) coupled with a correlation coefficient of 0.85, suggest that the model is generally accurate and reliable. The developed model would be useful, among other things, for solid-liquid equilibrium calculations in the absence of experimental ILs' melting point data as well as for the development of process simulators.
